# Effect of Nb doping on the performance of Li<sub>2</sub>RuO<sub>3</sub> cathodes

# **Next Generation Li-ion Battery Technology**

Lithium-ion battery technology, having the highest gravimetric and volumetric energy densities of commercialized batteries, has conquered the portable electronic market.<sup>1</sup> It is the battery of choice for powering electric vehicles and potential grid energy storage. Classical positive electrodes for Li-ion technology (LiMO<sub>2</sub> compounds) operate mainly through an insertion-disinsertion redox process involving cationic species. Next generation Li-rich layered oxides (Li<sub>2</sub>MO<sub>3</sub> compounds) are high-capacity materials where Li entails cumulative cationic ( $M^{n+} \rightarrow M^{(n+1)+}$ ) and anionic ( $O_2^- \rightarrow O_2^{2-}$ ) reversible redox processes, owing to the d-sp hybridization associated with a reductive coupling mechanism.<sup>2</sup>

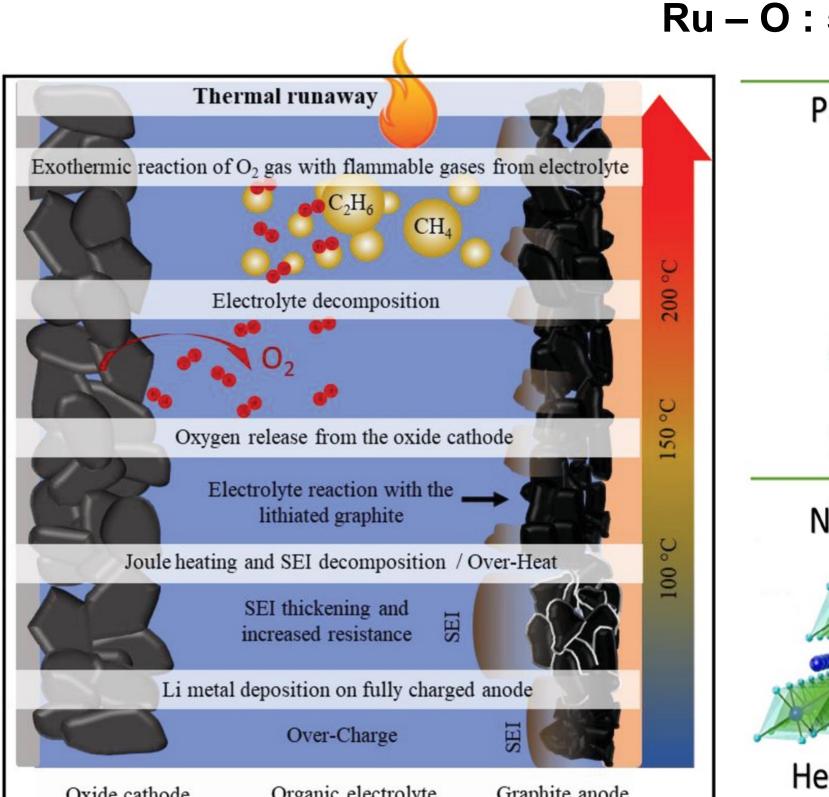

Industry standard: LiMO<sub>2</sub> 120 - 200 mAh g<sup>-1</sup>

## **State of the Art Cathodes**

Li-rich cathodes undergo structural rearrangement at high potential that evolve Batteries with doped with 1 mol% Nb exhibit higher capacity, yet it is unclear O<sub>2</sub>, lead to voltage fade, poor electrochemical kinetics, and safety concerns whether they can retain this capacity for more cycles than undoped cells. including thermal runaway. Nb dopant has a superior oxygen dissociation Literature values for Li<sub>2</sub>RuO<sub>3</sub> state that reversible capacity decreases from 240 energy and was proposed to stabilize the structure. mAh/g to ~140 mAh/g after 100 cycles. An inactive impurity, Li<sub>3</sub>NbO<sub>4</sub>, in 5 mol % Nb cells may lead to similar performances to undoped cells. **Nb – O : 727 kJ mol<sup>-1</sup> Co – O : 368 kJ mol**<sup>-1</sup> **Dissociation energies** Ni – O : 392 kJ mol<sup>--</sup> Ru – O : 528 kJ mol<sup>-1</sup> Effect of Nb on Capacity XRD Profiles Thermal runaway Pristine sample \*\*\*\*\* — 1% NI — 0% Nb Exothermic reaction of O2 gas with flammable gases from electrolyte 6000 ථි 200 · 5500 11110 150 · 5000 -~ . . . . . 🔵 Li Cycling Electrolyte decomposition ≦ 100 TM -- 1% Nb --- 5% Nb MO<sub>6</sub> --- 0% Nb 16 17 18 19 XRD of Li<sub>3</sub>NbO<sub>4</sub> Oxygen release from the oxide cathode Hexagonal layered phase Spinel phase 20 25 30 10 15 35 40 — 5% Nb Cycle Number ----- 1% Nb Electrolyte reaction with the \_\_\_\_\_ — 0% Nb lithiated graphite Nb doped sample Li2RuO3 XRD Profiles Joule heating and SEI decomposition / Over-Heat ----- 1% Nb 18.46 18.11 7000 — 0% Nb SEI thickening and increased resistance 5000 Li metal deposition on fully charged anode ° Cycling ↑**1.9**% Over-Charge 3000 + \_\_\_\_ 23 24 10 20 30 40 50 60 70 80 Hexagonal layered phase Hexagonal layered phase 2 Theta Graphite anode Organic electrolyte Oxide cathode (001) (001)Ming, Lei, et al. # Structure-Performance Relationships in Nb-doped Li<sub>2</sub>RuO<sub>3</sub>

### Material Synthesis and Electrochemical Cycling

To determine the optimal amount of Nb dopant, several compositions were synthesized through a solid state reaction. Dry precursors (RuO<sub>2</sub>, Li<sub>2</sub>CO<sub>3</sub>, Nb<sub>2</sub>O<sub>5</sub>) were mixed in stochiometric ratios, with 10% excess Li<sub>2</sub>CO<sub>3</sub> to account for material volatilization. After several grinding and heating steps the samples were characterized with XRD. Samples containing 1 mol% Nb and 5 mol% Nb were tested against a control of pure Li<sub>2</sub>RuO<sub>3</sub>. These samples were mixed with 10 wt% PVDF binder and 10 wt% SP carbon cast over aluminum foil, assembled into coin cells against Li metal, and cycled at C/10.
